Abstract

A specimen of *Boops boops*, 402 mm in total length (986 g weight), was caught on 27 March 2018 by gill net from Güllük Bay on the muddy bottom at a depth of 55 m. This record is the maximum size both for Turkish seas and Mediterranean basin.

Keywords: Bogue, maximum size, measurement, Güllük Bay, Aegean Sea

Akdeniz için Kupesin *Boops boops* (Perciformes: Sparidae) Maksimum Boyu

Özet

27 Mart 2018 tarihinde Güllük Körfezi’nde 55 m derinlikte çamurlu dip yapısında 402 mm TL (ağırlık 986 g) sahip bir adet *Boops boops* bireyi yakalanmıştır. Bu boyut hem Türk denizleri hem de Akdeniz için maksimum boy olarak kaydedilmiştir.

Anahtar kelimeler: Kupes, maksimum boy, ölçüm, Güllük Körfezi, Ege Denizi

INTRODUCTION

Bogue, *Boops boops* (Linnaeus, 1758), is a teleost fish species belonging to the Sparidae family. This species is mainly distributed in the eastern Atlantic, from Norway to Angola, common from the Bay of Biscay to Gibraltar and the Mediterranean Sea, including the Black Sea (Froese and Pauly, 2018). It also occurs in the western Atlantic in the Gulf of Mexico and the Caribbean Sea (Bauchot and Hureau, 1986).

The bogue is a medium sized species, commonly between 100- and 200-mm TL (Bauchot and Hureau, 1986) but with a reported maximum size of 400 mm from the Portuguese coast (Gordo, 1996). Maximum published weight is 455 g (Froese and Pauly, 2018). *B. boops* is inshore schooling demersal or semipelagic species that can be found in midwater above sandy, muddy or rocky substrate to a depth of 300 m (Bauchot and Hureau, 1986). This short paper reports a new maximum size of *Boops boops* for Mediterranean and Turkish waters.

MATERIAL and METHODS

On 27 March 2018, a specimen of *Boops boops* (Fig. 1) with 402 mm in total length and 986 g round weight was captured by a gill net (64 mm stretched mesh size) from Apostol islet (37°09'N-27°23'E) in Güllük Bay on muddy bottom at a depth of 55 m. The

specimen was measured to the nearest millimetre, fixed in 5% formaldehyde solution and deposited in the Ichthyological Collection of Ege University, Fisheries Faculty with the catalogue number: ESFM-PIS/2018-02. Description, measurements and percentage in total length (Table 1) of *B. boops* are in line with those reported by Bauchot and Hureau (1986) and Froese and Pauly (2018).

RESULTS and DISCUSSION

The specimen and the morphometric data reported the following ratios, as percent of TL or head length (HL): fork length 89.6%, standard length 83.3%, maximum body depth 23.4%, head length 17.4%, pre-dorsal length 26.4%, pre-anal length 54.7%, pre-pectoral length 17.7%, all in TL; eye diameter 20% in HL.

B. boops is a well-known sparid species all over the Turkish seas and several studies on the population structures of *B. boops* for both the Turkish seas and the Mediterranean are available in the literature (Table 1).

The maximum reported the size of 400 mm TL for the species (n=9244) was recorded by Gordo (1996) from the Peniche and Algarve coasts, Portugal. This size is also like that reported in the present study for both Turkish seas and the Mediterranean. Moreover, the present study also reported the maximum weight for the species (986 g), namely bigger more than double the maximum published weight, 455 g (Crec'hriou et al., 2013) in FishBase.

The huge *B. boops* was caught near a sea-cage fish farm by using gillnet for targeting bogue. Thus, the specimen of *B. boops* might be reaching the largest size via plenty of taking nourishment beneath the sea-cages. According to the length-weight relationship reported for the species by İlkyaz et al. (2008) the estimated weight for a specimen of 400 mm should be around 788 g. Froese (2006) stated that seasonal, geographic, climatic or other patterns in the variation of the condition factor should be used to explain within-species variation in weight-length relationships. Therefore, an abundance of food beneath the sea-cages can be the explanation for this excess of flesh.
